Hashing

MAY

'24

18th Week
125-241

04

SATURDAY

→ It is mainly used to implement dictionary, where you have key value pair, as well it also used when you set

Search

Insert $O(1)$ on average

Delete

→ Not useful for sorted environments. We use

- (a) finding closest values from AVL trees (or) Red Black tree.
- (b) sorted data goes from sorted to sorted to be (or)
- (c) prefix searching, binary search tree, etc.

Application of Hashing

preserving values into some data structure like list/dict/set and then fetching it.

(1) Dictionaries

(2) Database Indexing [hashing & B-tree]

(3) Cryptography (to hash) → In hashing, we always have

(4) Caches, Data Compression all need unique values, all values are unique.

(5) Symbol tables in compilers/interpreters unique. [It will

(6) Routers, Load Balancing. [It doesn't override previous case]

(7) Block chain, Image Processing.

(8) getting data from database first to root soft 30 and so on, nothing there. (or) of Hashing is a Technique

ReBt & HashTable is a Datastruc

2nd most used DS in Computer Science.

Direct Address Table

DAT is a DS that has the capability of mapping record to their corresponding keys using arrays. In direct address tables, records are placed using their key values directly as indexes. These facilitate fast searching, insertion and deletion operation.

MAY 2024

~~Advantages~~SUNDAY
08 Searching
Insertion
Deletion

09 (10)

10 Limitations :-

- (1) Prior knowledge of maximum key value.
- (2) Practically useful only if the maximum value is very less.
- (3) It causes wastage of memory spaces if there is a significant difference b/w total records and maximum value.

01 Hashing can overcome these limitations of direct address tables.

02 Ministyle Hash Functions

01 Hashing is a technique (or) process of mapping keys and values into the hash table by using a hash function. It's done for faster access to elements based on the position in slot function.

02 The efficiency depends on the hash function.

03 The task of hash function to convert those large keys, string, floating point number into small values that can be used as an index in the hash table.

- (a) Should always map a large key to some small key.
- (b) Should generate values from 0 to m-1. [m is size of hash table]
- (c) Should be fast, O(1) for integers and O(len) for strings of length 'len'.
- (d) Should uniformly distribute large keys into hash tables.

MAY

'24

19th Week
127-239

06

MONDAY

Example Hash function.

- ① $h(\text{large_key}) = \text{large_key \% m}$ (22, 15, 9, 27 & 10)
- ② for string weight sum $\text{str} = 'abcd'$

$$(str[0] * n^0 + str[1] * n^1 + str[2] * n^2 + str[3] * n^3) \% m$$

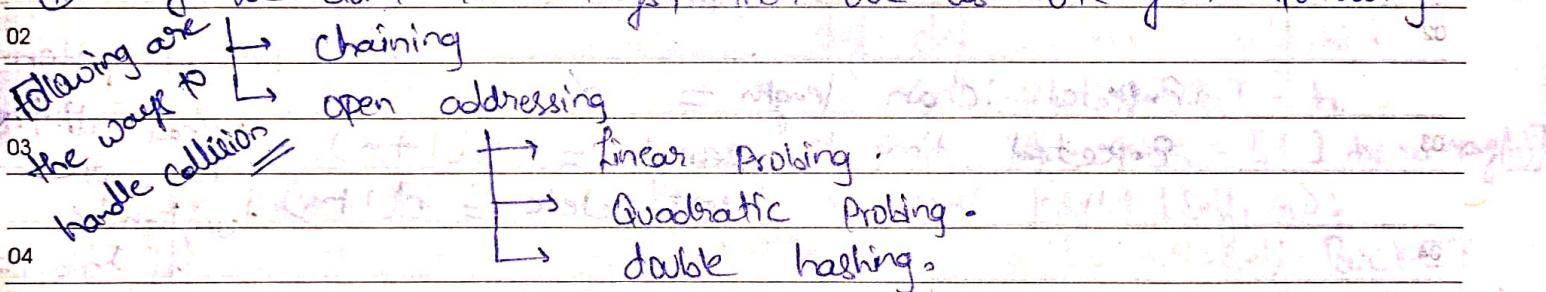

- ③ universal hashing.
- ↳ We choose Prime No which are not close to power.
 - Set of hash function, we have to pick randomly and good hash function

Collision handling

Birthday Paradox
23rd May

Collision is the conditions in which two keys map to the same entry in the hash table.

- If we know keys in advance, then we can go with perfect hashing.
- If we don't know keys, then we use one of the following.

- Chaining (Separate Chaining):
- The idea behind separate chaining is to implement the array as a linked list called a chain.
 - The linked list data structure is used to implement this technique, so what happens is when multiple elements are hashed into the same slot index, then these elements are inserted into a singly linked list which is known as chain.

→ We have array of linked list headers, whenever a collision happens you insert and item at the end of linked list.

5	[]	56, 72	[]	[56]	
6	[]		[]	[21]	

12

[[], [], [], [], [], [], []]

01

hash = m%BUCKET

h = myHash(7)

class MyHash:

h.insert(70)

def __init__(self, b):

h.insert(71)

b = 7, self.BUCKET = b

h.insert(9)

self.table = [[] for i in range(b)]

h.insert(56)

def insert(self, n):

h.insert(72)

Inserion i = m%self.BUCKET

print(h.search(56))

for i in range(m): self.table[i].append(n)

h.remove(56)

def remove(self, n):

h.search(56)

i = m%self.BUCKET

o/p - True

self.table[i].remove(n)

False

def search(self, n):

Searchable

i = m%self.BUCKET

method : (m) return n in self.table[i]

If (n in self.table[hash]): return True else: return False

if (n in self.table[hash]): return True else: return False

if (n in self.table[hash]): return True else: return False

if (n in self.table[hash]): return True else: return False

if (n in self.table[hash]): return True else: return False

if (n in self.table[hash]): return True else: return False

- ⑥ dict() → It is used to create empty dictionary.
- ⑦ len() → return the no. of items in each dictionary.
- ⑧ clear() → to remove all element from dictionary.
- ⑨ get() → to get the value associated with the key.
- ⑩ pop() → It remove the entry associated with the specified key and return the corresponding value.
- ⑪ item() → It remove arbitrary item from the dictionary and returns it.
- ⑫ keys() → It returns all keys associated with dictionary.
- ⑬ values() → It returns all values associated with dictionary.
- ⑭ items() → It returns list of tuples representing key-value pairs.
- ⑮ copy() → to create exactly duplicate dictionary (Cloned copy).
- ⑯ get default(): → to set default value in dictionary.

~~Q~~ n = [5, 3, 2, 2, 1, 5, 5, 7, 5, 10]
 m = [10, 11, 1, 9, 5, 6, 7, 2]

Brute force

```
for i in m:  

    count = 0  

    for j in n:  

        if i == j:  

            count += 1  

    print(count)
```

Optimal Solution

$Tc = O(mn)$
 $Sc = O(1)$

$K = \text{def}$ { hash-list = [0] * len(n) }
 for i in n: In this case
 hash-list[i] += 1
 $Tc = O(m+n)$
 $Sc = O(\text{len}(n)) // O(1)$

Above solution will only work when the elements of list is not varying time to time and prior we know all those element.

else we have to do this question using dictionary

dictionary sol

```
d = {}  

for i in n:  

    if i in d:  

        d[i] += 1  

    else:  

        d[i] = 1  

for i in m:  

    if i in d:  

        print(d[i])  

    else:  

        print(0)
```

~~Q~~ we have to find the elements of m appears how many times in n.

hash-list = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

Initially all are occurring zero times that's why we are keeping 0.
 then we are searching that element in hash-list
 (a) if it is there then incrementing its value by 1.

$T = O(n) + O(m)$ or $O(n+m)$ element in list
 0 time occurrences

$K = O(m)$

for i in m:
 if i < 1 or i > 10:
 print(0)
 else:
 print(hash-list[i])

For some question we they will ask us about character then also we can implement it using above methods.

S = "azzyyzaaaa"
 q = ["d", "a", "y", "z"]

$M-1$ same as above [Brute force]
 $M-2$ same as above but we will be using ascii value of each character to find out the same.

M-2

hash-list =

0	0	0	0	0	...	0	0	0	0
0	1	2	3			2	2	4	2

n { hash-list = [0]*26
 for i in s:
 ascii_value = ord(i)
 index = ascii - 97
 hash-list[index] += 1}

$$TC = O(n+m)$$

$$SC = O(1)$$

for i in q:
 ascii_value = ord(i)
 index = ascii_value - 97
 Print[hash-list[index]] } m

Q If the Question contains all upper case & lower case then apply dictionary method

d = {} {only for lowercase}

for i in s:
 if i in d:
 d[i] += 1
 else:
 d[i] = 1

for i in q:
 if i in d:
 Print(d[i])
 else:
 Print(0)

d = {} {for handling both upper & lower case}
 for i in s:
 if i in d:
 d[i] += 1
 else:
 d[i] = 1

for i in q:
 if i in d:
 Print(d[i])
 else:
 Print(0)

10

(S) (08) S = Set('FRIDAY')

08 A set is an unordered collection data type that is iterable, mutable and has no duplicate elements.

09 (a) Distinct elements will be stored.

(b) unordered.

10 (c) NO indexing is applied.

(d) Union, intersection, set difference etc are fast.

11 (*) (e) uses hashing internally.

12 (f) add() adds an element. S1 = {2, 4, 6, 8}, S2 = {3, 6, 9}

(g) update() adds elements. print(S1 | S2) → {2, 3, 4, 6, 8, 9}

01 (h) discard() removes an element. print(S1 & S2) → {2, 4, 6}

(i) remove() removes an element. print(S1 - S2) → {2, 4}

02 (j) clear() removes all elements. print(S1 & S2) → {}

len(S)

03 (*) (k) Intersection (l) difference (m) symmetric difference

union

04 (n) S1.union(S2), S1.intersection(S2), S1.difference(S2), S1.symmetric_difference(S2)

05 (o) Dictionary Key: Value pair

06 Dictionary is a collection of key values, used to store data value like a map, which unlike other data types which holds only single value or an element.

(a) unorderd.

(b) All keys must be distinct.

(c) Value may be repeated.

(*) (d) uses hashing internally.

d = {10: 'xyz', 101: 'abc', 105: 'bcd', 104: 'abc'}

→ Similar to hash map in Java, unordered map in C++.

del d[106]

d.popitem() → {101: lab, 106: bcd?}

~~Open addressing~~

→ Like separate chaining, open addressing is a method for handling collision. In open addressing, all elements are stored in the hash table itself. So at any point, the size of the table must be greater than or equal to the total number of keys. (Note that we can increase table size by copying old data if needed). This approach is also known as closed hashing.

The entire procedure is based upon probing, we will understand the types of probing ahead. (Cache friendly)

Ways of Implementing Open Addressing:

(a) Linear Probing:

Linearly search for next empty slot.

⇒ rehash(key) = (n+1) % table_size;

Subtract 1 from key if search in circular manner for next empty slot.

hash(key) = key % 7 is 10

insert(50), insert(51), insert(15)

Search(15), Search(64), delete(15)

MAY

'24

20th Week
133-233

12

Search — We compute hash function we go to that index and compare If we find, we return true; otherwise (d)

→ We linearly search through the table until we find the key → We stop when one of the three cases arise while searching:

(i) empty slot → mark it as False return false

(ii) key found → return true

(iii) traversed through the whole table → False

Delete — Problem with simply making slot empty when we delete so we don't mark the slot empty we mark it as deleted.

→ Now problem is if slot is deleted then what will happen if we insert again? $m \times m \rightarrow m^2$ slots

→ Primary clustering with linear probing.

→ To handle primary clustering problem with linear probing is $h(\text{key}) = \text{key} \% 7$ without wrap-around.

→ So hash function $h(\text{key}, i) = m(h(\text{key})) \% 7 + i \% 7 + 1$ and $i \in [0, 6]$

(i) Quadratic probing → $h(\text{key}, i) = h(\text{key}) + i^2 \% m$

(ii) Double hashing

→ $h(\text{key}, i) = h_1(\text{key}) + i \times h_2(\text{key}) \% m$

(a) Secondary clustering suffers by quadratic probing.

(b) It might happen that it doesn't find empty slot even if there are empty slot

(i) $\alpha < 0.5$ if load factor is less than 0.5 then only

(ii) you will able to find empty slot.

(iii) m is prime in (n/m) .

If two these things happen together then quadratic probing works and they will finds empty slot.

MONDAY

Refer book of CP and go through deal 3.4.27 261 → break

(b) Quadratic Probing : 2.1.6th slide 8 soft copy box

- 08 Quadratic Probing is a method by which we can solve the problem of clustering that was discussed above.
- 09 This method is also known as the mid-square method.
- In this method we look for the i^2 th slot in the i th iteration.
- 10 We always start from the original hash location. If only the location is occupied then we check the other slots.

(c) Double hashing : 3.3.7th slide 10th slot 312

- 12 Double hashing is a technique that reduces clustering in an optimized way. $\text{hash}(\text{key}, i) = (\text{h}_1(\text{key}) + i \cdot \text{h}_2(\text{key})) \% m$
- 01 In this technique, the increments for the probing sequence are computed by using another hash function.
- 02 If we use another hash function $\text{hash}_2(n)$ and look for the $i \times \text{hash}_2(n)$ slot in the i th iteration.
- 03 (a) If $\text{h}_2(\text{key})$ is relatively prime to m , then it always finds a free slot if there is one.
- 04 (b) Distributes keys more uniformly than linear probing and quadratic probing.
- 05 (c) No clustering.

$$\text{hash}(\text{key}, i) = (\text{h}_1(\text{key}) + i \cdot \text{h}_2(\text{key})) \% m$$

14

TUESDAY

- # Performance Analysis of search
- ⑧ Cache Performance of chaining is not good because when we traverse a linked list, we are basically jumping from one node to another, all across the computer's memory.
- ⑨ like chaining, the performance of hashing can be evaluated under the assumption that each key is equally likely to be hashed to any slot of the table.

$$m = \text{No. of slots in hash table}$$

$$n = \text{No. of keys to be inserted in hash table.}$$

$$\text{Load factor } d = \frac{n}{m} \quad (0 < d \leq 1)$$

Expected time to search / insert / delete $\leq \frac{1}{d}$

$d = 1 - (1 - \alpha)$ fraction of the table left empty.

Unsuccessful search means when you have either traversed through the whole table or you ended up with an empty slot.

Disadvantages

- | | |
|---|---|
| ① It is simple to implement | ② It requires more computation. |
| ③ Hash table never fills up, we can always add more elements. | ④ It may become full. |
| ⑤ Less sensitive to hash function | ⑥ Extra care required for clustering. |
| ⑦ Cache performance of chaining is not good as keys are stored using linked list. | ⑧ It provides better cache performance as everything is stored in same table. |
| ⑨ extra spaces are required for linked list ($1 + \alpha$) | ⑩ might be needed to achieve same performance $\Rightarrow [1/(1-\alpha)]$ |
| ⑪ better fit technique | → old fit techniques |
| → It is used when frequency and no. of keys are not known. | → It is used when frequency of keys are known. |

already present in hash

return True

- Declare a variable sum, to store the sum of prefix elements.
- Traverse the array and at each index, add the element into the sum and check if this sum exists earlier. If the sum exists, then return true.
- Also, insert every prefix sum into map, so that later on it can be found whether the current sum is seen before or not.
- At the end return false, as no such subarray is found.

Longest common subarray with given sum.

We are given two binary subarray of same sizes.

ifp: arr1 = [0, 1, 1, 0, 0, 0, 0]

arr2 = [1, 0, 1, 1, 0, 0, 1]

ofp: 4

ifp: arr1 = [0, 1, 0, 1, 1, 1, 1]

arr2 = [1, 1, 1, 1, 1, 0, 1]

ofp: 6

Naive

def longestCommonFor(arr1, arr2):

res = 0

n = len(arr1)

for i in range(n):

sum1 = 0

sum2 = 0

for j in range(i, n):

sum1 += arr1[j]

if sum1 == sum2:

res = max(res, j - i + 1)

return res

$\begin{cases} Tc = O(n^2) \\ Sc = O(1) \end{cases}$

Efficient solution

The Problem is going to reduce into the problem of longest subarray with 0 sum in an array.

```
def longestSpan([arr1, arr2]):
```

n = len(arr1)

arr1 = [0]*n

for i in range(n):

arr1[i] = arr1[i] - arr2[i]

mydict = dict()

Rum = 0

max_len = 0

for i in range(n):

Rum += arr1[i]

if Rum == 0:

max_len = i + 1

if Rum in mydict:

max_len = max(max_len, i - mydict[Rum])

else:

mydict[Rum] = i

return max_len.

TC = O(n)

SC = O(n)

① Compute a difference array.

int temp[n]:

for i in range(0, n): i++

temp[i] = arr1[i] - arr2[i];

eg

arr1[] = [0, 1, 0, 0, 1, 0]

arr2[] = [1, 0, 1, 0, 0, 1]

temp[] = [-1, 1, -1, 0, 0, -1]

② Return length of the longest subarray with 0 sum in temp.

→ ④ We get 0 when values are same in both

Value in temp[] → ⑤ We get 1 when ~~arr1[i] = arr2[i]~~ and arr2[i] = 0

→ ⑥ We get -1 when arr1[i] = 0 and arr2[i] = 1.

longest consecutive subsequence

Given an array, we need to find the longest subsequence that has consecutive elements. These consecutive elements may appear in any order in the subsequence.

i/p: arr[] = [1, 9, 3, 4, 2, 20]

o/p: 4

Naive

```
def longest(arr):
```

n = len(arr)

arr.sort()

res = 1

curr = 1

TC = O(n^2) for i in range(1, n):

if arr[i] == arr[i-1] + 1:

curr += 1

else:

res = max(res, curr)

res = max(res, curr)

return res

TC = O(n^2)

SC = O(1)

Efficient

```
def longest(arr):
```

s = set()

res = 0

for i in arr:

s.add(i)

for i in arr:

if {i-1} not in s:

curr = 1

while (curr + i) in s:

curr += 1

res = max(res, curr)

return res

TC = O(n)

SC = O(n)

Given an array of size n and an integer k , find all elements in the array that appear more than n/k times.

e.g. $\text{arr} = [3, 1, 2, 2, 1, 2, 3, 3]$, $k=4$

O/p: $[2, 3]$ Here n/k is $8/4 = 2$ therefore {appear 3 times } greater than 2 {3 appear 2 times}

Naive M-1 ① Sort the given array/list
 $[10, 10, 10, 10, 20, 20, 30]$ $k=2$, $n=7$, $n/k=3$

② Traverse through the sorted

10: 4 Print (10)

20: 2

30: 1

$T_C = O(n)$
 $S_C = O(n)$

def Point nk (arr, k):

arr.sort()

i = 1

count = 1

while $i < \text{len}(arr)$:

{ while ($i < \text{len}(arr)$ and $\text{arr}[i] == \text{arr}[i-1]$)

count += 1

i += 1

if (count > n/k):

print (arr[i-1], end = " ")

Count = 1

i = i + 1

Count distinct element in every window

i/p: $[10, 20, 20, 10, 30, 40, 10]$, $k=4$

O/p: 2 3 4 3

i/p: $[10, 10, 10, 10]$, $k=3$

O/p: 1 1

Naive Approach

① There will be $(n-k+1)$ windows

$[10, 20, 10, 30, 40]$, $k=3$

② Traverse through every window and count distinct element in it.

def Point Distinct (arr, k):

n = len(arr)

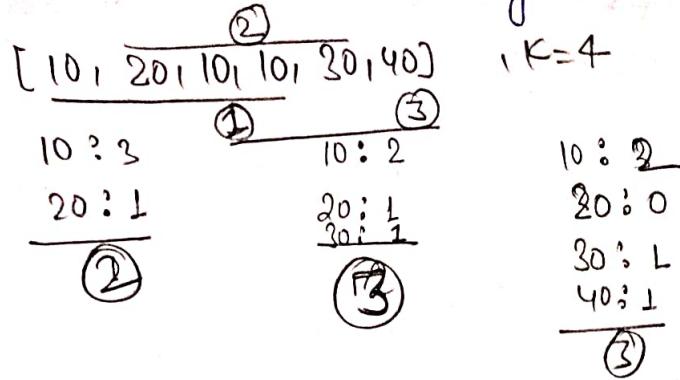

for i in range(n-k+1):

print (len(set(arr[i:i+k])))

$\left\{ \begin{array}{l} T_C = O((n-k+1) * k) \\ S_C = O(k) \end{array} \right\}$

Efficient

The idea is to use count of previous windows to get the current count.

longest Subarray with given sum.

Given an array arr[] of size n containing integers. The Problem is to find the length of the longest subarray having sum equal to the given value k.

eg. Naive

arr[] = {10, 5, 2, 7, 1, 9}, k=15
if i: 4 → Subarray is {5, 2, 7, 1}

def longestSum(arr, sum):

res = 0

for i in range(len(arr)):

curr = 0

for j in range(i, len(arr)):

curr += arr[j]

if curr == sum:

res = max(res, j - i + 1)

return res

Efficient

def longestSum(arr, sum):

n = len(arr)

mydict = dict()

pre-sum = 0

res = 0

for i in range(n):

pre-sum += arr[i]

if pre-sum == sum:

res = i + 1

if pre-sum not in mydict:

mydict[pre-sum] = i

from the collections I'm using Counter

from collections import Counter

def countDist(arr, k):

first window { mp = Counter(arr[0:k])
Print (len(mp))

Tc = O(n) for i in range(k, len(arr)):

sc = O(1)

{ n = arr[i-k] }
remove left item of prev window { mp[n] -= 1 }
if mp[n] == 0: del mp[n]
Add last item of current window { mp[arr[i]] += 1 }
Print (len(mp))

Tc = O(n^2)

Tc = O(n)
Sc = O(n)

→ if pre-sum - sum in mydict:

res = max(res, i - mydict[pre-sum])

return res
